design approach in integrated drives as one may affect the other significantly [3].

Abstract

In this paper, a multi-physics approach is presented for the design optimization of an integrated modular motor drive (IMMD) system. The system is composed of a modular permanent magnet synchronous motor and a GaN based modular motor drive power stage. The multi-physics model includes the motor drive inverters and DC link capacitor bank (electrical model), the stator windings and rotor magnets (electromagnetic model), the heat sink (thermal model) and a geometrical model. The main purpose of the design optimization is to obtain the highest power density, which is quite critical in integrated drives. As the system has several interdependencies due to integrated structure, selection of parameters is based on those relationships. A 8 kW IMMD system design is proposed and the resultant system is simulated using various simulation platforms for verification.

1 Introduction

Conventional variable frequency motor drive systems are composed of two distinct parts: the drive and the motor, where drive units are placed in separate cabinets and connected to the corresponding motors with long cables. This causes reduction in the overall system power density, cost increase and electromagnetic interference (EMI) problems [1]. In integrated modular motor drive (IMMD) systems, the drive is integrated onto the motor back iron forming a single package such that the power density of the overall system is enhanced and the connection cables are eliminated [1]. Furthermore, each pole of the motor is driven by its own drive module which are then interconnected via a common DC link. By doing so, the fault tolerance of the system is increased, heat dissipation is spread on a wider surface area and voltage stress on windings and power semiconductor devices are reduced [2].

In IMMDs, the space available for the drive system components is drastically reduced due to integration. Therefore, fitting all the components requires design optimization with integrated model approach and careful spatial and layout design. Moreover, the interdependencies between the main system components yields a multi-physics approach where the design of motor, drive power electronics and thermal management system should be considered all together. Therefore, it is highly difficult to propose a decoupled

The current IMMD prototypes proposed in the literature are usually based on new generation wide band-gap power semiconductor devices, such as Gallium Nitride (GaN) power FETs [4]. These devices are capable of switching at much higher switching frequencies compared to their silicon counterparts with low switching losses [5]. It is possible to reduce the size of passive components with high switching frequencies as well as reduce the size of heat sink with superior efficiency values with the utilization of enhancement mode (e-mode) GaNs. Considering that the largest components on an average power converter system are passive components and the heat sink [1], utilization of these devices is critical for IMMD designs. Moreover, thanks to the modularity of the system, interleaving technique can be used to further reduce the size of DC link capacitor bank [6]. Although several studies have been published regarding power electronics design, modular inverter topologies, DC link capacitor selection etc. for IMMDs [1,3,7,8], most of these prototypes lack a unified design. One example for such a dependency is that, the cross-sectional area available for the motor drive printed circuit board (PCB) and heat sink is determined by the diameter of the motor.

In this paper, optimum design of an IMMD system is presented considering both the motor and drive parameters to obtain the highest power density. It is also aimed to maximize the overall system efficiency which keeping the active material costs in acceptable limits. A permanent magnet synchronous motor (PMSM) having fractional slot concentrated winding (FSCW) stator is utilized for its superior torque density, low cogging torque and fault tolerance capability which makes it suitable for IMMD applications [9]. The content of the multi-physics design optimization approach includes electrical, electromagnetic, thermal and geometrical models. First, the multi-physics model is presented in Section 2. In section 3, the basic relations between the system parameters and the cost and constraint functions are obtained and the inter-dependencies are discussed. Using the results of Section 3, an optimum system design is proposed in Section 3. In Section 4, the presented models are verified and the proposed system design is evaluated using simulation results. The paper is concluded in Section 5.

2 System modelling

Motor drive integration onto the modular stator back iron is considered in this paper, an example of which is shown in Fig. 1 [7]. The structural configuration of the proposed system is also shown in Fig. 2.

Figure 1. An example of the IMMD structure [7]

Figure 2. Structural configuration of the proposed IMMD

The fundamental blocks of the system model and the coupling of different aspects used in the integrated design are shown in Fig. 3. Basically, the system is composed of the electrical model, electromagnetic model, thermal model and geometrical (spatial) model. The system specifications and constraints are listed in Table 1.

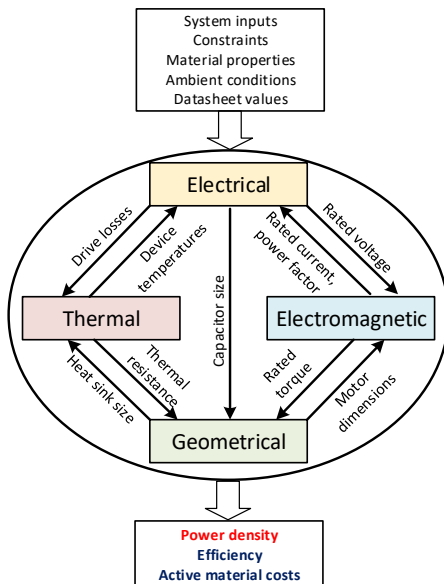

Figure 3. Fundamental blocks of the system model

Moreover, the independent variables and their corresponding sub-models are also shown in Table 2.

Parameter	Value
DC link voltage, V_{dc}	540 V
Number of phases in each module, m	3
Motor total output power, P_{out}	8 kW
Motor rated speed, N_r	600 rpm
Machine electric loading, A_{rms}	35 kA/m
Machine magnetic loading, B_{avg}	0.6 T
Maximum winding current density, J_{rms}	4 A/mm ²
Maximum stator teeth flux density, B_{ts}	1.8 T
Maximum stator yoke flux density, B_{ys}	1.4 T
Maximum fill factor, k_{cu}	0.6
Maximum device junction temperature, T_{j-max}	150 °C
Maximum capacitor temperature, $T_{cap-max}$	70 °C
Maximum DC link voltage ripple, V_{dc-r}	1 %
Minimum motor efficiency, η_{m-min}	94 %
Minimum drive efficiency, η_{d-min}	98 %
Minimum power factor, $\cos(\varphi)_{min}$	0.9
Ambient temperature, T_{amb}	50 °C

Table 1. System specifications and constraints

Optimization parameters	Sub-model
Number of modules, n	Electrical
Number of series modules, n_s	Electrical
Switching frequency, f_{sw}	Electrical
Modulation index, m_a	Electrical
Aspect ratio of the motor, α	Electromagnetic
Slot/module/phase, w_s	Electromagnetic

Table 2. Optimization parameters (independent variables)

The IMMD system has a modular structure where each three-phase inverter module drives its own part of the stator pole. The modules can be connected in series and/or parallel configuration via a common DC link. A block diagram of the system is shown in Fig. 3 with 2-series and 2-parallel connected modules.

Figure 3. A general block diagram of the IMMD

2.1 Electrical sub-model

The electrical model includes, determination of rated parameters of the motor drive inverter, selection of power semiconductor devices, calculation of motor drive losses,

determination of required DC link capacitor parameters and selection of DC link capacitors. A set of 650V e-mode GaN FETs suitable for high voltage applications having different current ratings from GaN systems are used for the design [ref]. The devices are selected from these commercial products based on the number of series and parallel modules (n_s , n_p), modulation index (m_a), power factor ($\cos(\varphi)_{min}$) and motor efficiency (η_{m-min}) limitations. By using the selected device parameters, the motor drive losses are determined as shown in (1) for forward conduction loss, (2) for reverse conduction loss, (3) for switching loss, where E_{on} , E_{off} and E_{oss} are the on state, off state and output capacitance switching energies, respectively, R_{ds-on} is the on state resistance, I_p is the peak line current. All of the datasheet parameters are calibrated according to operating temperature, voltage and current.

$$P_{cf} = I_p^2 R_{ds-on} [1/8 + m_a \cos(\varphi)_{min} / (3\pi)] \quad (1)$$

$$P_{cr} = I_p^2 R_{ds-on} [1/8 - m_a \cos(\varphi)_{min} / (3\pi)] \quad (2)$$

$$P_{sw} = [E_{on} + E_{off} + E_{oss}] f_{sw} / \pi \quad (3)$$

The analytical models for the determination of required capacitance (C_{dc}) and RMS current rating (I_{c-rms}) for a typical inverter are given in (4) and (5), where I_{rms} is the rms line current [ref]. For a modular motor drive, it is possible to use interleaving technique to reduce these requirements. The effect of interleaving is determined by proper phase shifting angle for each possible case using computer simulations and added to the capacitance and ripple current requirements. It has been shown that series connection has no effect on the ripple current and ripple voltage for any phase shifting angle. The normalized effect of interleaving on these parameters is shown in Fig. 5.

$$C_{dc} = \frac{I_{rms} m_a}{16 f_{sw} V_{dc-r}} \sqrt{(6 - 96\sqrt{3}/5\pi + 9m_a^2/2) \cos(\varphi)^2 + 8m_a \sqrt{3}/5\pi} \quad (4)$$

$$I_{c,rms} = I_{rms} \sqrt{[2m_a (\sqrt{3}/4\pi + \cos(\varphi)^2 (\sqrt{3}/\pi - 9m_a/16))]} \quad (5)$$

Figure 5. The effect of interleaving for parallel connected modules

A database of film capacitors are used from commercial products [ref] for capacitor selection model which is based on the capacitance, ripple current and DC voltage requirements. The selected capacitor is used to test whether its core temperature exceeds the specified limit or not, by using the implicit thermal model expressed in [ref] and capacitor

datasheet values such as ESR, thermal conductance etc. Temperature dependency is especially critical since it affects the lifetime of the capacitors significantly. The capacitor dimensions are used in the geometrical model. The required phase induced voltage per module (E_{phm}), which is the link between the electrical and electromagnetic models is determined using the inverter model as in (6).

$$E_{phm} \approx 0.612 m_a V_{dc} \cos(\varphi)_{min} / (\sqrt{3} n_s) \quad (6)$$
